## List of Appendices

Appendix A June 2010 Analytical Data, August 2010 Off Site Well Analytical Data

## 1.0 Introduction

This report is the first of two reports for the INVISTA Spartanburg site groundwater and surface water data collected in June 2010. This report details the data that was collected and provides an update on the overall environmental conditions at this time. The data was gathered based on agreements reached during the meeting held at the South Carolina Department of Health and Environmental Control (DHEC) offices on February 2, 2010 and subsequent communications.

A Sampling and Analysis Plan (SAP) for the work was submitted in April 2010 and was approved by DHEC on June 1. The June sampling plan approved under the SAP is included as Table 1 of this report. The June sampling event was completed as detailed in Table 1. The groundwater and surface water sample locations are presented in Figure 1.

Groundwater elevations measured during the June 2010 event are presented in Table 2. Groundwater data collected during June 2010 is summarized in Table 3 and surface water data is presented in Table 4. Only parameters detected in at least one sample are included in Tables 3 and 4. Results of 1,4-dioxane analyses in surface water were included in Table 4 even though there were no detections. The complete laboratory reports are included as an appendix to this report.

## 2.0 Groundwater Elevations

Groundwater elevations were collected from wells throughout the site. The groundwater elevation data is presented in Table 2. Potentiometric Maps were developed based on the June elevation data. Separate potentiometric maps were developed for wells screened in saprolite and wells screened in bedrock. Some of the wells at the site were placed at the transition from saprolite into bedrock and data from these wells were included in both maps. The potentiometric map for saprolite is presented in Figure 2. The potentiometric map for bedrock is presented in Figure 3.

Groundwater in saprolite flows away from the site in two general directions, with a divide running near the approximate center of the plant area. Groundwater north of this divide flows toward the Cherokee Creek. Groundwater south of the divide flows toward the Pacolet. A significant transitional area is present in the region of the former sludge holding area and former DMT equalization basin. Groundwater in this region flows either toward the Cherokee Creek or the Pacolet River depending on how far north or south the location. However, water throughout the transition flow is biased toward the conflux of the two surface water features. Groundwater flow along the southern end of the site tends to flow in a more southern direction, which is consistent with the immediate local topography.

The majority of groundwater wells screened in bedrock are located along the site perimeter and in the central plant area. Therefore the resolution of potentiometric contours is not as precise as it is for the saprolite data. In general the flow follows a similar pattern as for saprolite, though the divide is not as significant and flow is biased toward the Pacolet River more than is seen for saprolite. The observation of bedrock groundwater flow being biased toward the Pacolet is consistent with expectations because the river is a deeply incised feature immediately adjacent to the site.

### 3.0 1,4-Dioxane

Results of analyses for 1,4-dioxane are presented in Figures 4 and 5.

Detections of 1,4-dioxane in saprolite are noted in the central plant area and downgradient of the former Fiber 1 EQ Basin. Detections are also noted in these same areas in bedrock, as well as the former sludge drying lagoon area and downgradient of the former DMT equalization basin.

Surface water data is included in the saprolite data on Figure 4. Surface water sampling was modified for this event. Historically, surface water samples have been collected "mid/mid", meaning they are collected away from the stream bank and approximately halfway between the water surface and stream bed. DHEC stated during the February 2 meeting that this method may not be appropriate for site conditions. If 1,4-dioxane is discharged into the stream along the bank, a relatively concentrated band could persist along the bank with minimal mixing. Samples collected at the mid-point of the stream could potentially be removed from this band and not be representative of conditions near the bank and in the hyporheic zone. The SAP proposed that surface water samples would be collected directly at the water edge and at the stream bed. The surface water samples collected in June 2010 were collected as described in the SAP. All 1,4-dioxane results in surface water samples were non-detect (<0.01 mg/L).

The locations of detections of 1,4-dioxane are consistent with the assessment presented in the 2001 Operating Strategy Report. The Operating Strategy Report included estimates of impact to surface water and determined that the flux of 1,4-dioxane into the Pacolet River and Cherokee Creek would not result in significant concentrations. UV-oxidation of dilute concentrations in surface water is expected to attenuate remaining 1,4-dioxane mass over a period of days, depending on the degree of exposure to direct sunlight.

Because the data supports the conclusions of the Operating Strategy Report, continued monitoring as recommended in that report is appropriate for 1,4-dioxane.

70 state uses cause  
of DL

## 4.0 DowTherm A™

DowTherm A™ is comprised of biphenyl ether and 1,1-biphenyl. Biphenyl ether represents the larger fraction and also degrades less rapidly than 1,1-biphenyl. Therefore concentrations of biphenyl ether are both more frequent and higher than the concentrations of 1,1-biphenyl.

The results of analyses of biphenyl ether in saprolite and bedrock are presented in Figures 6 and 7.

As described in the Operating Strategy Report, phase DowTherm A™ is extracted from well MW-7, which is located downgradient from the central plant area. Approximately 77 gallons of phase material has been extracted from this well since the extraction was initiated in August 2001.

The data presented in Figures 6 and 7 indicate that DowTherm A™ remains present in the central plant area and at lower concentrations downgradient of the Fiber 1 EQ Basin.

Monitoring of DowTherm A™ will be continued and extraction from well MW-7 will also be continued.

## 5.0 Chloroform and other Volatile Organics

Chloroform is the primary volatile organic compound identified at the site. Enhanced reductive dechlorination (ERD) through the injection of lactate has been employed in the former DMT area to address the chloroform plume which was identified in this area.

Previous reports have detailed the ERD activities. Concentrations of chloroform prior to injection were up to a maximum of 15 mg/L. The extent and magnitude of detections have been significantly decreased since the injection activities were completed.

June 2010 chloroform concentrations are presented in Figures 8 and 9.

The highest concentration reported was 0.478 mg/L at saprolite well MW-109. Saprolite wells are mostly non-detect (<0.005 mg/L), with the exception of a small region between the southern edge of the treatment area and the MW-109 location. Bedrock wells are almost entirely non-detect, with the exception of two wells. All of the chloroform detections in bedrock wells and in saprolite wells outside of the region south of the treatment are below the total trihalomethane MCL of 0.080 mg/L.

DHEC also requested that six downgradient, off-site properties be investigated for the presence of wells and sampled for chloroform if wells were present. These properties were identified as having "limited" or "minimal" chance for chloroform impact in the Receptor Survey submitted earlier this year.

Three of the properties were determined to have no well present. These properties are the undeveloped property at 545 Conway Black Road, the Transfer Case Express property (former Bruckner Industries) property at 600 Bruckner Road, and the "Music Camp" property at 190 Childress Road. Public water is available at both the Transfer Case Express and "Music Camp" properties.

The other three properties are each residential properties. The property at 611 Bruckner has a well which has been sampled twice before, in 2002 and 2006. Each of the previous times the well was non-detect for chloroform. The properties at 615 Bruckner Road and 175 Childress Road were also found to have wells. At each these two properties there is a well, but the residence is on public water. One of the two properties uses the well for agricultural use. The other property no longer uses its well.

All three wells were sampled in August 2010. In each of the three events the result of analysis for chloroform was non-detect (<0.005 mg/L). The laboratory analytical data for these samples is included in Appendix A. The samples were identified as Spartanburg-001, Spartanburg-002, and Spartanburg-003.

Other volatiles organic parameters were generally not detected above reporting limits. The detections for volatile compounds other the chloroform are presented in Figures 10 and 11.

Low detections of tetrachloroethene were noted at two wells in saprolite. Trichloroethene and cis-1,2-dichloroethene were also detected in one of these two wells and cis-1,2-dichloroethene was also detected in three other wells. Two of these three wells are transition zones wells and are therefore presented on both Figures 10 and 11.

On the north side of the property a detection of 1,1-dichloroethene was noted at transition well EW-27 and several chlorinated organics were detected in bedrock well EW-14 near Lake Patrick.

Detections of acetone were noted at bedrock wells EW-31 and RW-109. 2-Butanone was also noted at well RW-109. Each of these compounds is believed to be associated with the ERD treatment. Concentrations of these parameters have been reported in other wells during the remediation process and have rapidly attenuated. Since injection at well RW-108 the concentrations have been more than an order of magnitude higher than currently reported and continued attenuation is expected. The detection of acetone at well EW-31 is slightly above the reporting limit and acetone has not been detected at this well since 2006. Acetone is also a common lab contaminant.

## 6.0 Attenuation Parameters

Most attenuation parameters were monitored only in the former DMT area. Other parameters are routinely collected as part of the sample collection procedure. The results of attenuation parameter monitoring are presented in Figures 12 through 33.

Dissolved oxygen data is presented on Figures 12 and 13. The contours on these figures present areas of depressed oxygen concentrations. A large area of depressed oxygen concentration is noted in and around the former DMT area. This condition is expected as part of the ERD treatment process.

Areas of depressed oxygen are also noted in the central plant area, downgradient of the fiber 1 EQ basin, and beneath the former sludge drying lagoon area. Aerobic degradation of DowTherm A™ components is thought to be the primary cause of depressed oxygen concentrations in these areas.

ORP readings are presented on Figures 14 and 15 with areas of reduced ORP designated by the contours. The areas of reduced ORP are consistent with the areas of suppressed dissolved oxygen presented on the prior two figures. The one significant distinction is a gap in the suppressed ORP measurements in saprolite in the southern edge of the former DMT area. This location is consistent with the area of chloroform detections as shown in Figure 8.

Dissolved ferrous iron and dissolved manganese concentrations are presented in Figures 16 through 19. Elevated concentrations of these parameters are indications of biological activity and reduced conditions. As with the prior figures, the contours indicate activity in the former DMT area as well as the central plant area, Fiber 1 EQ Basin, and former sludge drying lagoon. Contours outside of the former DMT area are not present on Figures 18 and 19 because manganese was not monitored away from this area.

Sulfate and sulfide results are presented in Figures 20 through 23. These parameters are only monitored in the former DMT area. Sulfate is converted to sulfide under reducing conditions and depending on other factors sulfide can precipitate out of solution. Neither parameter was frequently detected.

Nitrate and Nitrite results are presented in Figures 24 through 27. These parameters are only monitored in the former DMT area. Nitrate is converted to nitrite under reducing conditions. Detections of nitrate were noted primarily in saprolite in the same region with chloroform detections. There were no detections of nitrite. Because the detections of nitrate correspond to the area of chloroform detections, it is likely that nitrate was present at other locations but has been reduced and nitrite is either precipitated or further reduced through denitrification.

Orthophosphate data is presented on Figures 28 and 29. Detections of orthophosphate were infrequent and low.

Alkalinity results are presented on Figures 30 and 31. Increased alkalinity is an indicator of biological activity. Alkalinity is higher in bedrock and highest at well RW-108. These results are consistent with the minimal detections of chloroform in bedrock and that RW-108 was the most recent location of injection.

Total organic carbon (TOC) concentrations are presented on Figures 32 and 33. Detections of TOC are at generally low levels throughout the former DMT area. During ERD treatment TOC concentrations were measured at thousands of milligrams per liter (mg/L). The much lower levels of TOC remaining indicate that the treatment period is complete, as is expected for the amount of time that has passed since injection activities were completed.

In summary, the attenuation data supports the previously established conclusion that the ERD process has been effective in creating reductive conditions capable of treating the chloroform plume.

## 7.0 Receptor Survey Update

SCDHEC has requested that the previously submitted receptor survey be updated to include properties to the East of the Pacolet River. The receptor survey is updated in Figure 34 and Table 5.

North of Interstate 85 the property across the Pacolet River is part of the Invista property.

The two northernmost properties on the southern side of Interstate 85 are undeveloped. The remaining properties are residential. Public water is available to these properties. The residential properties are on the far side of a significant dogleg in the Pacolet River. The local geology that creates this dogleg feature is expected to significantly limit groundwater flow from the direction of the plant to these properties. Therefore the potential for any impact from the chloroform plume to the groundwater at these locations is considered to be highly remote.

## 8.0 Summary and Plan Forward

This report provides the data collected in the June 2010 sampling event and a summary of the current site conditions.

The primary parameters of interest at the site are 1,4-dioxane, DowTherm A™ (1,1-biphenyl and biphenyl ether), and chloroform.

Plumes of 1,4-dioxane and DowTherm A™ are comparable to the assessment as presented in the Operating Strategy Report and Preliminary Risk Evaluation. These parameters remain below detectable levels in surface water samples.

Chloroform has been significantly reduced in concentrations and extent as a result of the ERD treatment program. Chloroform does not exceed the MCL in any of the bedrock sample locations. Elevated concentrations of chloroform in saprolite are limited to a region in the southern edge of the former DMT area and through the MW-109 area. Non-detections in off-site wells downgradient and west of the remaining detections indicate that the plume does not extend in that direction.

A Remedial Effectiveness report will be submitted in November. The Remedial Effectiveness report will review previous site conditions and remedial activities to date. Additional actions will be recommended based on the assessment. This report will be submitted by November 30, 2010.

The Remedial Effectiveness report will include an updated recommendation for groundwater and surface water monitoring in 2011. The recommendations will revise the monitoring wells planned for sampling based on the conclusions of both this report and the Remedial Effectiveness assessment. Sulfide, sulphate, and orthophosphate will be removed from the parameter list because the limited detections of these parameters indicate that continued analysis is not justified.

The December sampling event will be completed as described in the SAP. A report summarizing the results of this event will be submitted by March 31, 2011.

Description	:INVISTA SPARTANBURG SITE

---

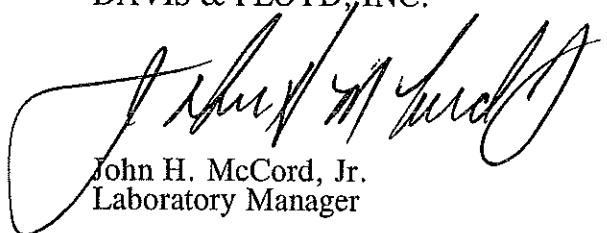

Dear Bryon Dahlgren:

We are pleased to provide the enclosed analytical results for the samples received by Davis & Floyd, Inc. on August 12, 2010.

A formal Quality Assurance/Quality Control program is maintained by Davis & Floyd, which is designed to meet or exceed the EPA, NELAC or other appropriate regulatory requirements. All analytical analyses for this project met QA/QC criteria and the results are within the 99% confidence interval for each method unless otherwise stated in the footnotes. This report is to be reproduced only in full.

Feel free to contact our Client Services Representative at (864) 229-4413 if further explanation of the analysis is required. Unless other arrangements have been made, samples will be disposed of or returned 14 days from the date of the report. We appreciate the opportunity to provide services to your firm.

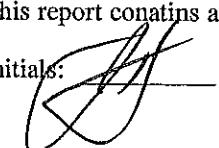

Sincerely,  
DAVIS & FLOYD, INC.

John H. McCord, Jr.  
Laboratory Manager

**Explanation of Symbols and Abbreviations**

The following defines common symbols and abbreviations used in reporting technical data:

RDL	Report Detection Limit	MDL	Method Detection Limit
PQL	Practical Quantitation Limit	DL	Detection Limit
LOQ	Limit of Quantitation	LOD	Limit of Detection
SQL	Sample Quantitation Limit	TIC	Tentatively Identified Compound
C	Degrees Centigrade	F	Degrees Fahrenheit
umhos/cm	micromhos/cm	meq	milliequivalents
su	Standard Units		

**mg/l, mg/kg** Units of concentration in milligrams per liter for liquids and milligrams per kilogram for solids. Also referred to as Parts Per Million or "ppm".

**ug/l, ug/kg** Units of concentration in micrograms per liter for liquids and micrograms per kilograms for solids. Also referred to as Parts Per Billion or "ppb".

< Less Than

> Greater Than

Solid samples (i.e. soil, sludge, and solid waste) are reported on an as received basis unless otherwise noted.

**Data Qualifiers:**

- B Analyte also detected in the method blank.
- C Amendable Cyanide is a negative value due to an unknown interference.
- J The reported result is an estimated value (eg matrix interference observed or concentration outside the quantitation range).
- N Non-target analyte. The analyte is TIC (using mass spectrometry).
- P Concentration difference between primary and confirmation columns >25%.
- Q One or more quality control criteria failed (e.g., LCS recovery, surrogate spike recovery or CCV)
- U Final concentration is below the detection limit.
- \* Defined in report comments.

Test results relate only to the sample tested. Clients should be aware that a critical step in a chemical or biological analysis is the collection of the sample. Unless the sample analyzed is truly representative of the bulk of the material involved, the test results will be meaningless. If you have any questions regarding the proper techniques of collecting samples, please contact us. However, we cannot be held responsible for sample integrity unless sampling has been performed by a member of our staff.

**REPRESENTATION AND LIMITATION OF LIABILITY** – The accuracy of all analytical results for samples begins as it is received by the laboratory. Integrity of the sample begins at the time it is placed in the possession of authorized Davis & Floyd, Inc. Laboratories personnel. All other warranties, expressed or implied, are disclaimed. Liability is limited to the cost of the analysis.

# DAVIS FLOYD
